Module 1.a – Lecture Summary

Introduction to Web Application Technologies

Web applications are software applications accessed through web browsers. They allow users to interact with online services, manage data, and access information from different devices.

A web application consists of three main components:

- **Frontend:** Provides the user interface using HTML, CSS, and JavaScript.
- **Backend:** Processes requests and implements application logic.
- **Database:** Stores and manages application information.

How a Web Application Works

1. The user enters a URL.
2. The browser sends an HTTP/HTTPS request.
3. The web server receives the request.
4. The backend processes it.
5. The backend may retrieve or update database information.
6. The server sends a response.
7. The browser displays the result.

Web Application Security

Important security mechanisms include Authentication, Authorization, Input Validation, Session Management, Data Protection, and HTTPS.

These mechanisms help protect user information and secure communication between the browser and server.
